

RASPBERRY PI BASICS

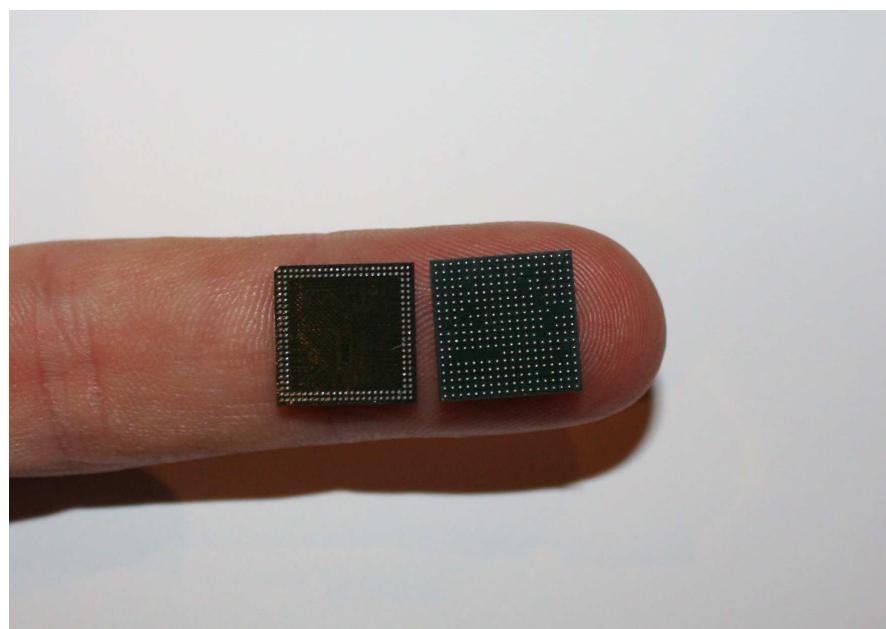

System on Chip (SoC)

- What is System on Chip?
 - A complex IC that integrates the major functional elements into a single chip or chipset.
 - programmable processor
 - on-chip memory
 - accelerating function hardware (e.g. GPU)
 - both hardware and software
 - analog components
- Benefits of SoC
 - Reduce overall system cost
 - Increase performance
 - Lower power consumption
 - Reduce size

SoC in Raspberry Pi: Broadcom BCM2835 SoC Multimedia processor

- CPU
 - ARM 1176JZF-S (armv6k) 700MHz
 - RISC Architecture and low power draw
 - Not compatible with traditional PC software
- GPU
 - Broadcom Video IV
 - Specialized graphical instruction sets
- RAM
 - 512MB (Model B rev.2)
 - 256 MB (Model A, Model B rev.1)

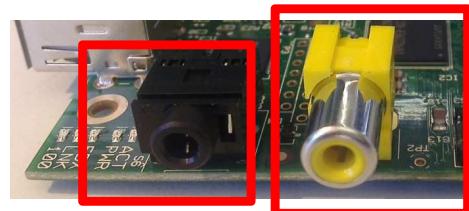

SoC in Raspberry Pi: Broadcom BCM2835 SoC

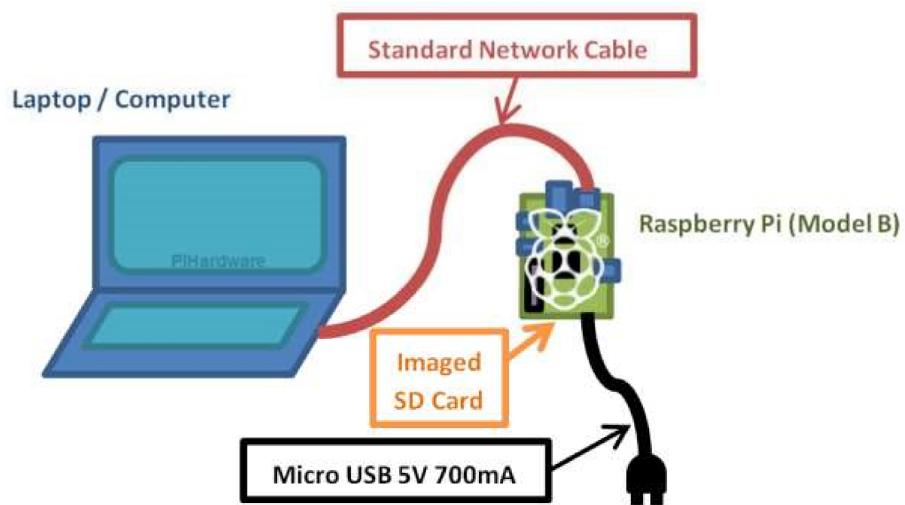

BCM2835 SoC (right) and Samsung K4P2G324ED Mobile DRAM (left)

Connecting a Display and Audio

- HDMI
 - Digital signal
 - Video and audio signal
 - DVI cannot carry audio signal
 - Up to 1920x1200 resolution
- Composite RCA
 - Analog signal
 - 480i, 576i resolution
- 3.5mm jack

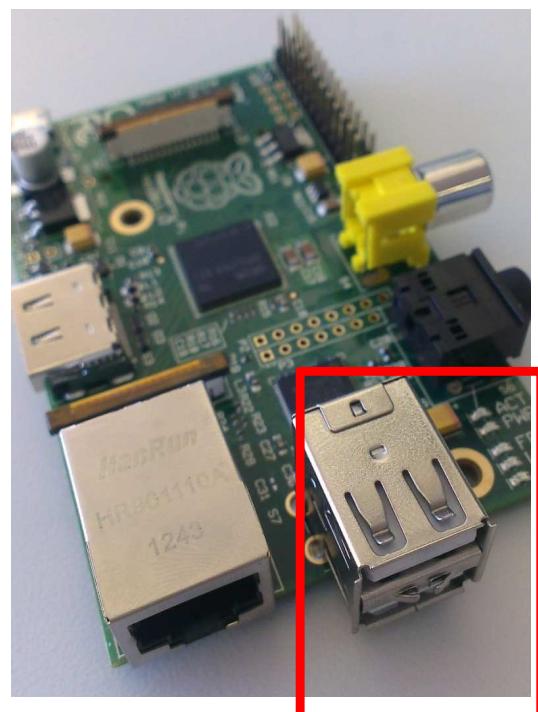

RPi Remote Connections

<http://pihw.wordpress.com/guides/direct-network-connection/>

Universal Serial Bus

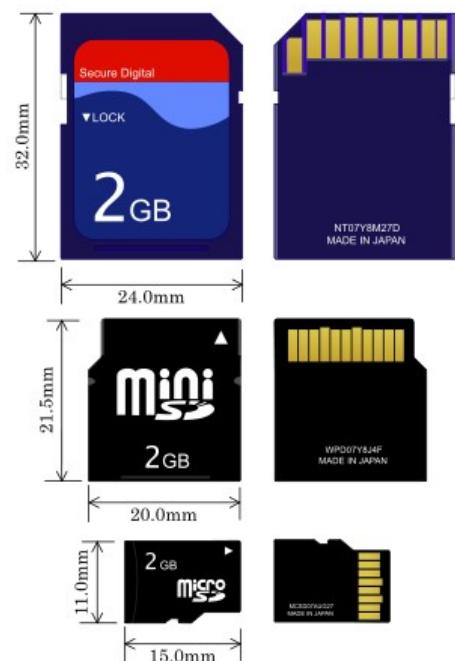

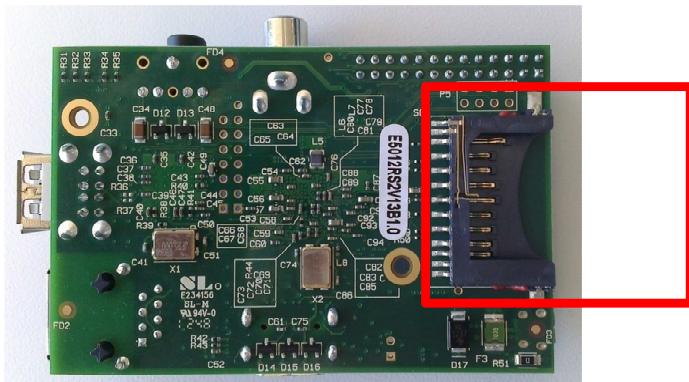

- Two USB 2.0 ports in RPi
- Buy a powered USB hub

Passive models are cheaper and smaller, but lack the ability to run current-hungry devices like CD drives and external hard drives.

Storage: Secure Digital (SD)

- Form factor
 - SD, Mini SD, Micro SD
- Types of Card
 - SDSC (SD): 1MB to 2GB
 - SDHC: 4GB to 32 GB
 - SDXD up to 2TB

The card should be at least 2GB in capacity to store all the required files

Storage: Continue

SD Formatter:

https://www.sdcard.org/downloads/formatter_4/

How to mount USB flash drive from command line:

<http://linuxcommando.blogspot.co.uk/2007/12/how-to-mount-usb-flash-drive-from.html>

Networking

Ethernet (IEEE 802.3)

USB Ethernet Converter

Wi-Fi Adapter

Networking - wireless

- IEEE 802.11 Wi-Fi
 - Protocols
 - 802.11 b, up to 11Mbps
 - 802.11 g, up to 54Mbps
 - 802.11 n, up to 300Mbps
 - 802.11 ac (draft), up to 1Gbps
 - Frequency band
 - 2.4GHz, 5GHz

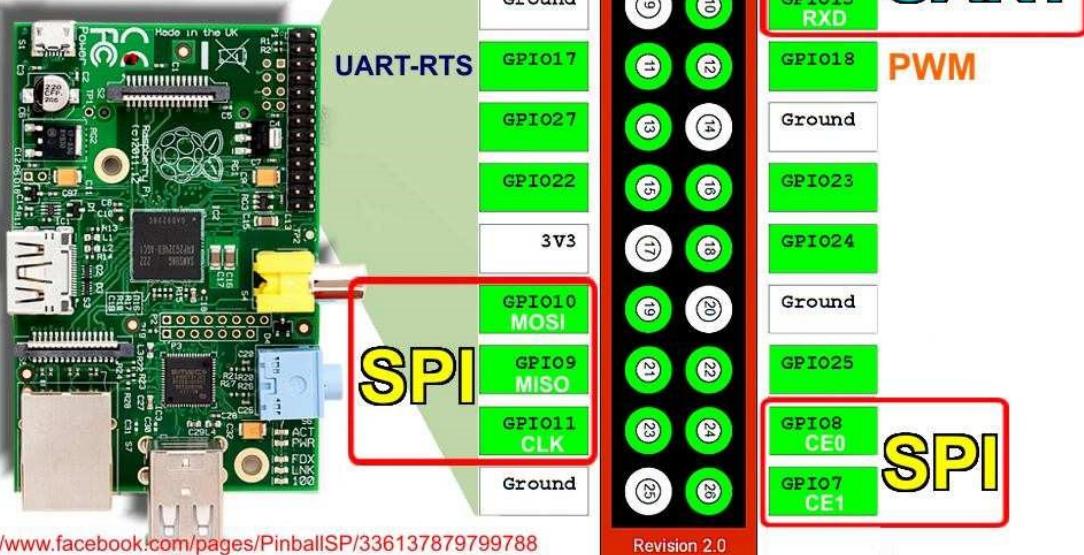

Low Speed Peripherals

- General Purpose Input/Output (GPIO)
 - Pins can be configured to be input/output
 - Reading from various environmental sensors
 - Ex: IR, video, temperature, 3-axis orientation, acceleration
 - Writing output to dc motors, LEDs for status.

RASPBERRY PI Revision 2 Pinout

<http://www.pinballsp.com>

<https://www.facebook.com/pages/PinballSP/336137879799788>

Power Consumption

- microUSB power connector
 - 2.5W (model A)
 - 3.5W (model B)
- Powered USB hub
 - To provide more power for USB peripherals

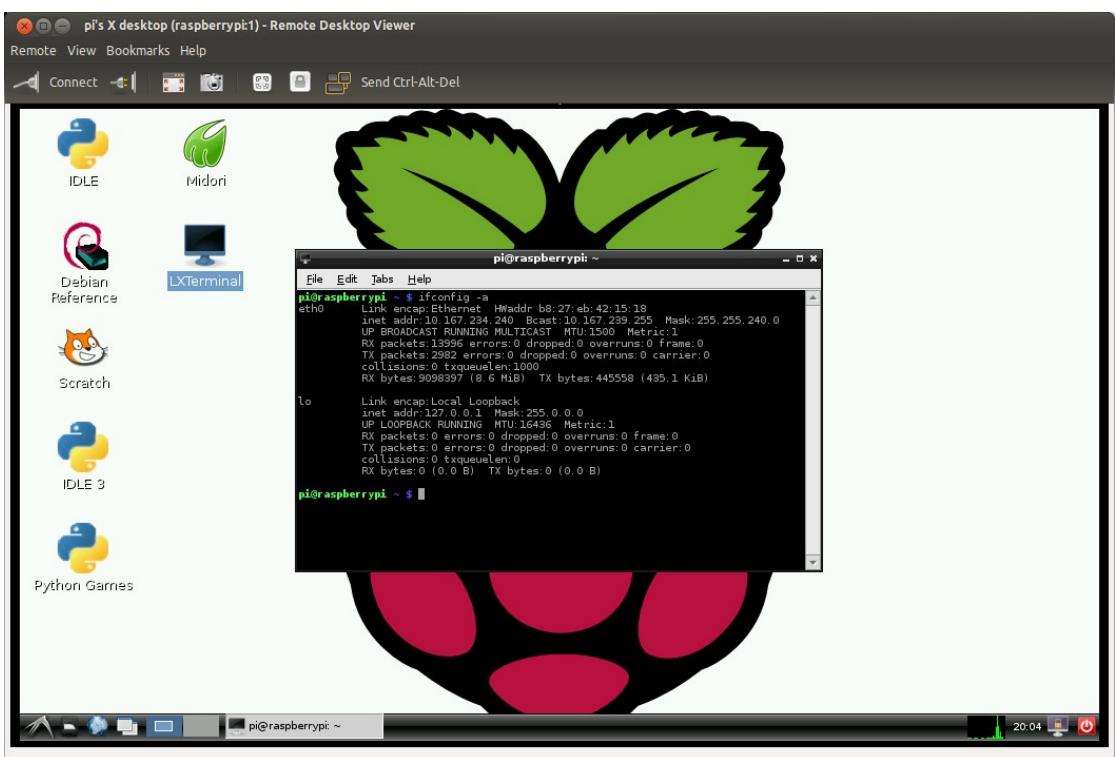

Useful links

- The MagPi
 - <http://www.themagpi.com>
- Raspberry Pi on Adafruit Learning System:
 - <http://learn.adafruit.com/category/learn-raspberry-pi>

Raspberry Pi Setup

- 1. Download the Raspberry Pi operating system
 - Linux releases compatible with the Pi:
<http://www.raspberrypi.org/downloads>
 - The recommended OS is Raspbian:
http://downloads.raspberrypi.org/raspbian_latest
- 2. Unzip the file that you just downloaded
 - Right click on the file and choose “Extract all”.
 - Follow the instructions—you will end up with a file ending in .img

- 3. Download the Win32DiskImager software
 - a) Download `win32diskimager-binary.zip` (currently version 0.6) from:
<https://launchpad.net/win32-image-writer/+download>
 - b) Unzip it in the same way you did the Raspbian `.zip` file
 - c) You now have a new folder called `win32diskimager-binary`

- 4. Writing Raspbian to the SD card
 - a) Plug your SD card into your PC
 - b) In the folder you made in step 3(b), run the file named Win32DiskImager.exe
 - c) If the SD card (Device) you are using isn't found automatically then click on the drop down box and select it
 - d) In the Image File box, choose the Raspbian .img file that you downloaded
 - e) Click Write
 - f) After a few minutes you will have an SD card that you can use in your Raspberry Pi

- 5. Booting your Raspberry Pi for the first time
 - On first boot you will come to the Raspi-config window
 - Change settings such as timezone and locale if you want
 - Finally, select the second choice: **expand_rootfs** and say ‘yes’ to a reboot
 - The Raspberry Pi will reboot and you will see raspberrypi login:
 - Username: pi, password: raspberry
 - Start the desktop by typing: **startx**
 - The desktop environment is known as the Lightweight X11 Desktop Environment (LXDE)

Raspi-config

info	Information about this tool
expand_rootfs	Expand root partition to fill SD card
overscan	Change overscan
configure_keyboard	Set keyboard layout
change_pass	Change password for 'pi' user
change_locale	Set locale
change_timezone	Set timezone
memory_split	Change memory split
ssh	Enable or disable ssh server
boot_behaviour	Start desktop on boot?
update	Try to upgrade raspi-config

<Select>

<Finish>

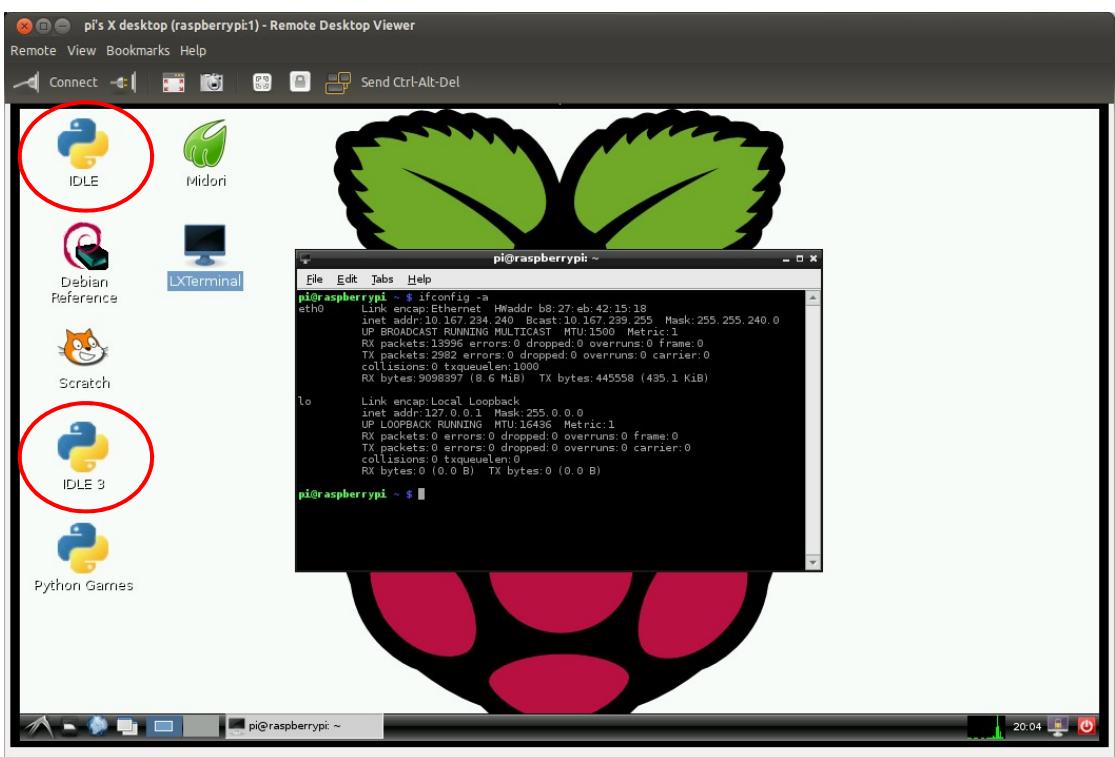

Re-mapping Keyboard:

- sudo vi /etc/default/keyboard
XKBLAYOUT="gb"
Change "gb" to "us"
- (This assumes you want a us mapping, if not replace the gb with the two letter code for your country)

Install and Start SSH

- Update apt-get package index files:
 - sudo apt-get update
- Install SSH:
 - sudo apt-get install ssh
- Start SSH server:
 - sudo /etc/init.d/ssh start
- To start the SSH server every time the Pi boots up:
 - sudo update-rc.d ssh defaults

- SSH client for Windows:
 - PuTTY
 - <http://www.putty.org/>
- SSH Secure File Transfer
 - http://www.utexas.edu/learn/upload/ssh_client.html

Install Java

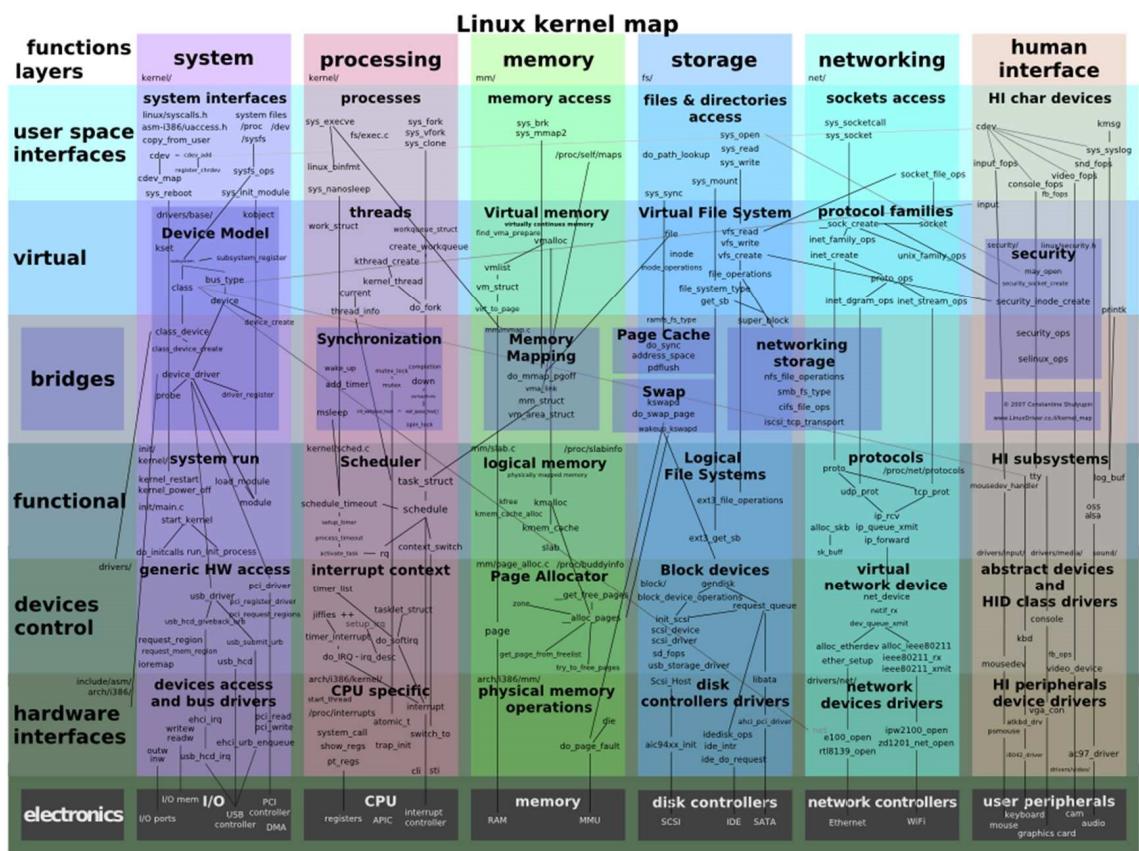

- 1. JDK 8 (with JavaFX) for ARM Early Access
<http://jdk8.java.net/fxarmpreview/>
 - Download from Raspberry pi
 - Download from your own PC and copy it (scp) to Raspberry pi
- Extract the JDK tar.gz file
 - tar -zxvf fileToExtract.tar.gz
 - You will get a folder “jdk1.8.0”

Set Java PATH

- If you put the folder “jdk1.8.0” in the home directory (i.e. /home/pi), you will see the java executables (e.g. javac, java, appletviewer) in the directory: /home/pi/jdk1.8.0/bin
- open /etc/profile
add:
`PATH=$PATH:/home/pi/jdk1.8.0/bin
export PATH`
- Reboot:
`sudo reboot`

Linux System Administration

Kernel and Distribution

Kernel and Distribution

Although only the kernel itself is rightly called Linux, the term is often used to refer to a collection of different open-source projects from a variety of companies. These collections come together to form different flavors of Linux, known as distributions.

File System Logical Layout

boot: This contains Linux kernel and other packages needed to start the Pi

bin: OS-related binary files, like those required to run the GUI, are stored here.

dev: Virtual directory, which doesn't actually exist on the SD card. All devices connected to the system can be accessed from here.

etc: This stores miscellaneous configuration files, including the list of users and their encrypted passwords

home: Each user gets a subdirectory beneath this directory to store all their personal files

lib: This is a storage space for libraries, which are shared bits of code required by different applications.

lost+found: A special directory where file fragments are stored if the system crashes.

media: A special directory for removable storage devices, like USB memory sticks or external CD drives.

File System Logical Layout

mnt: This folder is used to manually mount storage devices, such as external hard drives.

opt: This stores optional software that is not part of the OS itself. If you install new software to your Pi, it will usually go here.

proc: Another virtual directory, containing information about running programs which are known in Linux as processes.

selinux: Files related to Security Enhanced Linux, a suite of security utilites originally developed by the US National Security Agency.

sbin: Stores special binary files, primarily used by the root account for system maintenance.

sys: This directory is where special OS files are stored.

tmp: Temporary files are stored here automatically.

usr: This directory provides storage for user accessible programs.

var: This is virtual directory that programs use to store changing values or variables.

Software

LXTerminal and Root Terminal: use the Linux command line in a window without leaving the GUI.

Midori & NetSurf: Lightweight web browser

IDLE and IDLE 3: IDE for Python 2.7 and 3

Task Manager: Checks the available memory, processor workload, closes crashed or unresponsive programs

Music player at the console: moc

OpenOffice.org: sudo apt-get install openoffice.org

Image Editing: Gimp

LAMP (Linux, Apache, MySQL and PHP) stack

Sudo apt-get install apache2 php5 php5-mysql mysql-server

Installing, Uninstalling and Updating Software

- Package manager in Debian: apt
 - GUI for apt, Synaptic Package Manager doesn't work well on Pi due to the lack of memory
- Make sure that the apt cache is up to date:
 - apt-get update
- Finding software:
 - apt-cache search emacs
- Installing software and dependencies:
 - sudo apt-get install emacs
- Uninstalling software:
 - sudo apt-get remove emacs
 - sudo apt-get purge emacs (removes everything including configurations)
- Upgrading software:
 - Sudo apt-get upgrade
 - Sudo apt-get install emacs

Troubleshooting

Keyboard and Mouse Diagnostics

Power Diagnostics

Display Diagnostics

Network Diagnostics

Emergency Kernel

Wired Networking Configuration

```
sudo nano /etc/network/interfaces
```

```
iface eth0 inet static
[tab] address 192.168.0.10
[tab] netmask 255.255.255.0
[tab] gateway 192.168.0.254
```

```
sudo /etc/init.d/networking restart
```

```
sudo nano /etc/resolv.conf
```

```
nameserver 8.8.8.8
nameserver 8.8.4.4
```

```
sudo /etc/init.d/networking restart
```

```
ping -c 1 www.raspberrypi.org
```

Wireless Networking Configuration

- USB Wi-Fi adapters are very power-hungry. Connect a powered USB hub to the Pi, and then insert the Wi-Fi adapter into that.
- Print out the entire kernel ring buffer and find out the company that makes the actual chip: mesg | grep ^usb

Atmel-firmware
Firmware-atheros
Firmware-brcm80211
Firmware-intelwimax
Firmware-ipw2x00
Firmware-iwlwifi
Firmware-ralink
Firmware-realtek
Zd1211-firmware

- Check the current status of the network: iwconfig

Configuring the Raspberry Pi

RPi doesn't have a BIOS menu. It relies on text files containing configuration strings that are loaded by the chip when powers on.

- Hardware settings: config.txt
- Memory Partitioning: start.elf
- Software Settings: cmdline.txt

References for Python

Beginner's Guide to Python

<http://wiki.python.org/moin/BEGINNERSGUIDE>

A free, interactive tutorial

<http://www.learnpython.org>

Learn Python the Hard Way (Shavian Publishing, 2012)

Dive Into Python 3 (APRESS, 2009)

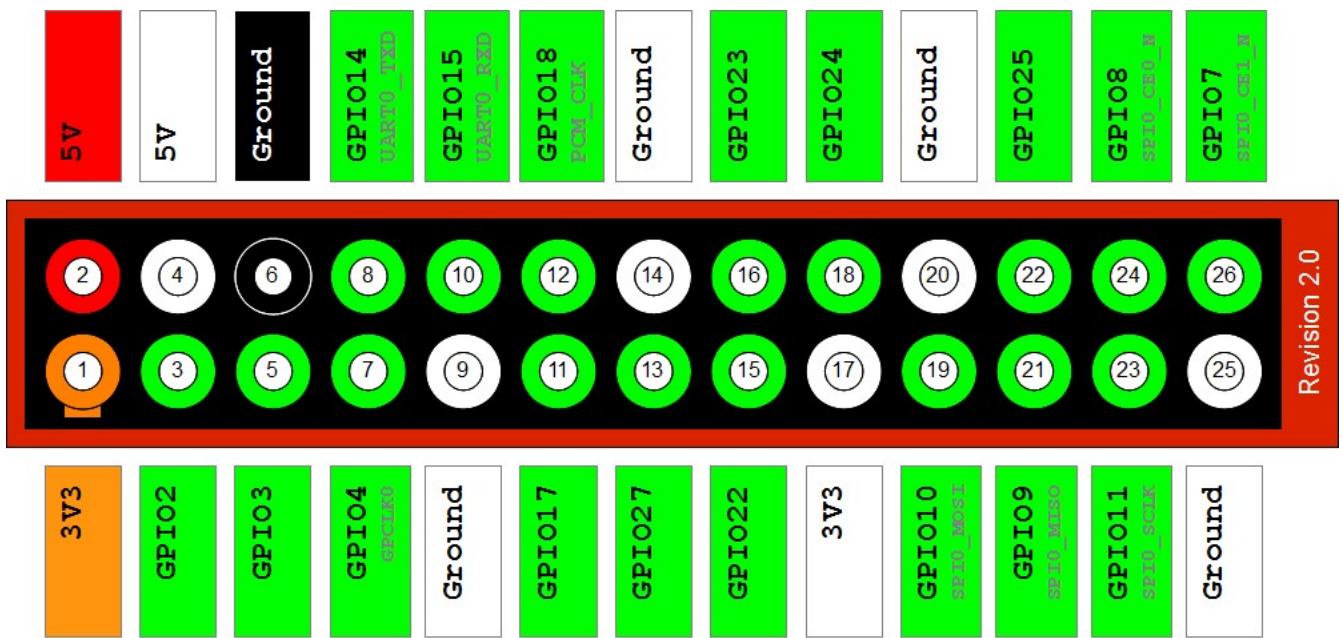

General Purpose Input/Output (GPIO)

- General Purpose Input/Output (GPIO) is a generic pin on a chip whose behavior can be controlled by the user at run time.

- The GPIO connector has a number of different types of connection:
 - True GPIO (General Purpose Input Output) pins that you can use to turn LEDs on and off etc.
 - I2C interface pins that allow you to connect hardware modules with just two control pins
 - SPI interface with SPI devices, a similar concept to I2C but uses a different standard
 - Serial Rx and Tx pins for communication with serial peripherals

- GPIO pins can be used as both digital outputs and digital inputs.
- Output: turn a particular pin HIGH or LOW.
 - Setting it HIGH sets it to 3.3V; setting it LOW sets it to 0V.
- Input: detect the pin being at HIGH or LOW
 - we can connect switches and simple sensors to a pin and check whether it is open or closed (that is, activated or not)

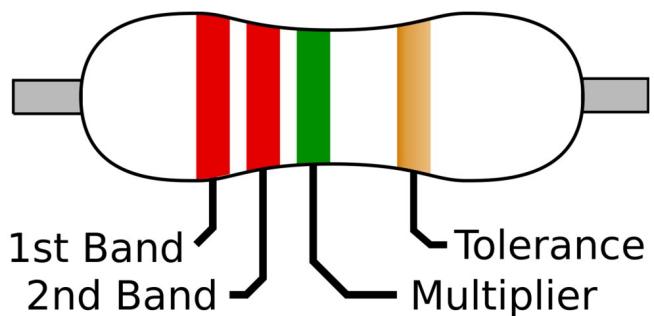

To use the pin numbers from the ribbon cable board:
`GPIO.setmode(GPIO.BCM)`

To use the pin numbers on raspberry pi board
`GPIO.setmode(GPIO.BOARD)`

All the pins have 3.3V logic levels and are not 5V-safe so the output levels are 0-3.3V and the inputs should not be higher than 3.3V.

Electronic Equipment

- Breadboard
 - Components in the same row are connected together without wires
- Jumper Wires
 - Try to use different colors to differentiate different purposes
- Resistors
- Push-Buttons
- LEDs

	1st/2nd Band	Multiplier	Tolerance
Black	0	$\times 10^0$	-
Brown	1	$\times 10^1$	$\pm 1\%$
Red	2	$\times 10^2$	$\pm 2\%$
Orange	3	$\times 10^3$	-
Yellow	4	$\times 10^4$	-
Green	5	$\times 10^5$	$\pm 0.5\%$
Blue	6	$\times 10^6$	$\pm 0.25\%$
Violet	7	$\times 10^7$	$\pm 0.1\%$
Grey	8	$\times 10^8$	$\pm 0.05\%$
White	9	$\times 10^9$	-
Gold	-	$\times 10^{-1}$	$\pm 5\%$
Silver	-	$\times 10^{-2}$	$\pm 10\%$
None	-	-	$\pm 20\%$

GPIO setup on Raspberry Pi

- Install Python 2 library Rpi.GPIO.
 - A library that will let us control the GPIO pins.
- <https://pypi.python.org/pypi/RPi.GPIO>
- Install commands:

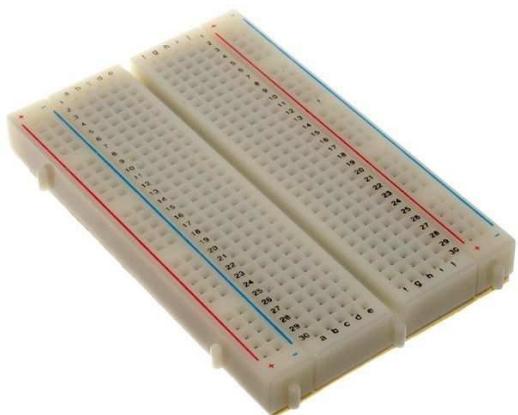

```
sudo apt-get update
sudo apt-get install python-dev
sudo apt-get install python-rpi.gpio
```

GPIO as Output

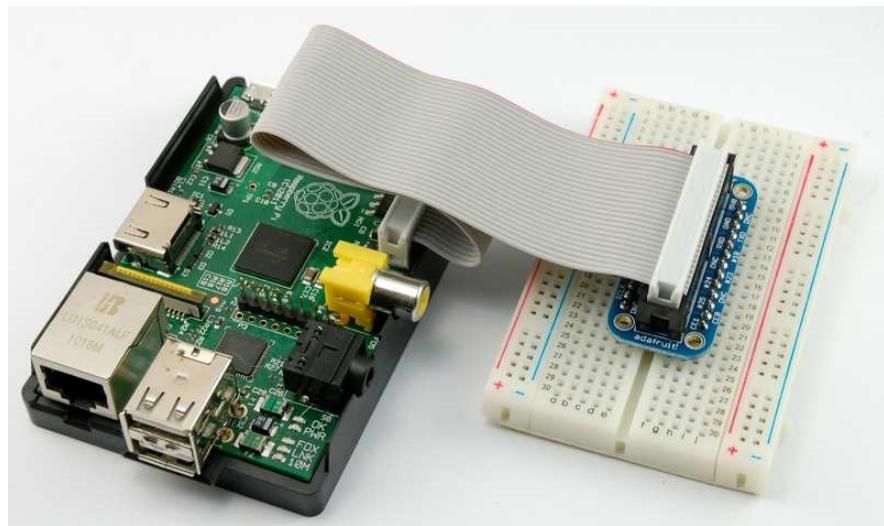

- Experiment 1: Controlling LED
 - LED
 - Breadboard
 - Jumper wire

Breadboard

- Build circuit easily without soldering

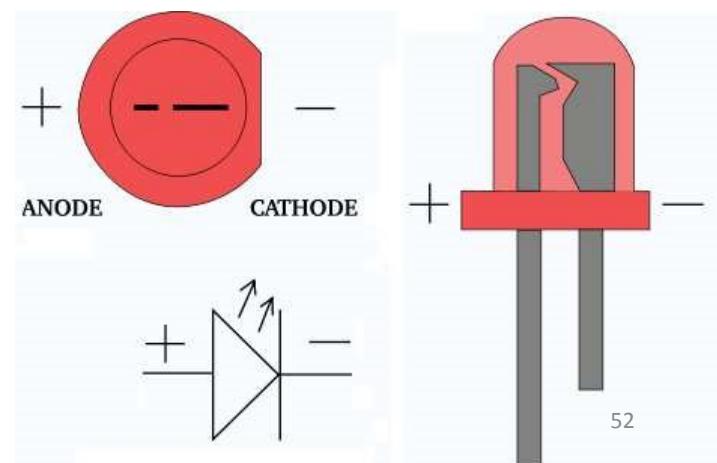

Use Cobbler kit to extend the GPIO to breadboard

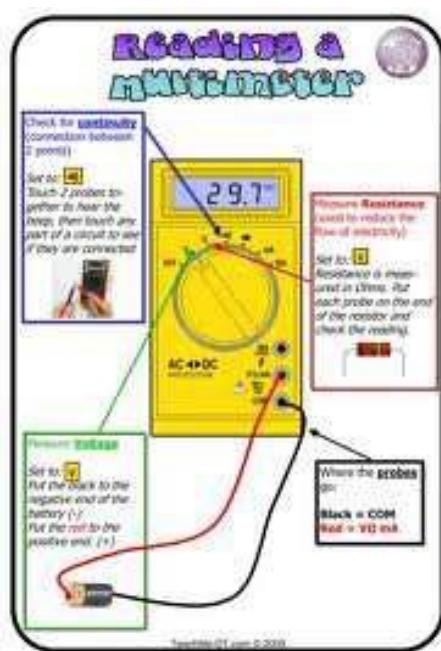

Light-emitting diode (LED)

- Current flows from the anode to cathode.
 - Anode: longer pin
 - Cathode: shorter pin
- Use a multimeter to test the polarity
 - Check resistance
 - In both directions.

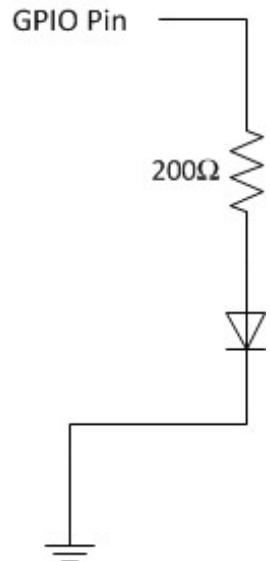

Multimeter

Task 1: Turn LED on for 2 seconds and off for 1 second, loop forever

- In this example, we control the LED by controlling the voltage at the anode (+).

Code for task 1

```
import RPi.GPIO as GPIO
import time

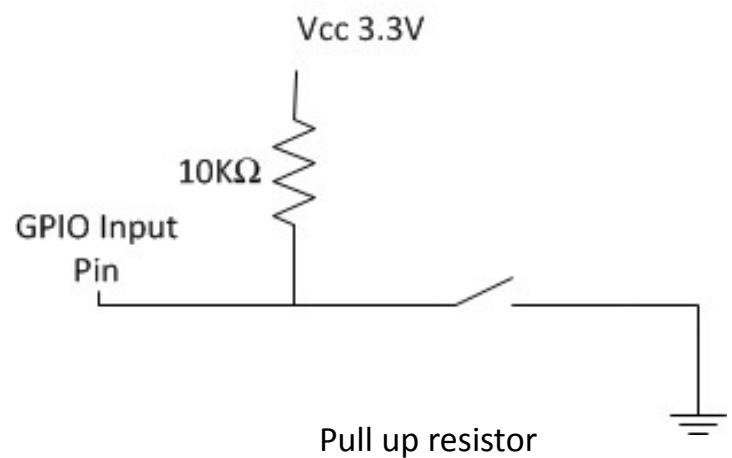

def main():
    GPIO.cleanup()
    GPIO.setmode(GPIO.BOARD) # to use Raspberry Pi board pin numbers
    GPIO.setup(11, GPIO.OUT) # set up GPIO output channel

    while True:
        GPIO.output(11, GPIO.LOW) # set RPi board pin 11 low. Turn off LED.
        time.sleep(1)
        GPIO.output(11, GPIO.HIGH) # set RPi board pin 11 high. Turn on LED.
        time.sleep(2)

main()
```

GPIO as Input

- When the switch is not pushed: GPIO detects Vcc (HIGH)
- When the switch is pushed: GPIO detects GND (LOW)

GPIO Input Sample Code

- `import RPi.GPIO as GPIO`
- `# Use the pin numbers from the ribbon cable board`
`GPIO.setmode(GPIO.BCM)`
- `# Set up this pin as input.`
`GPIO.setup(17, GPIO.IN)`
- `# Check the value of the input pin`
`GPIO.input(17)`
- `# Hold down the button, run the command again. The`
`output should be "true".`
`GPIO.input(17)`

Check input using polling

```
input = True
prev_input = True

while True:
    input = GPIO.input(17)

    if (prev_input and (not input)):
        print("Button pressed")

    #update previous input
    prev_input = input

    #slight pause to debounce
    time.sleep(0.05)
```

Check input using call back

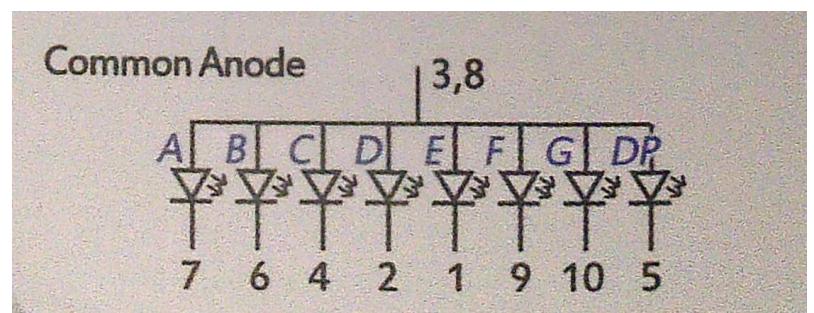

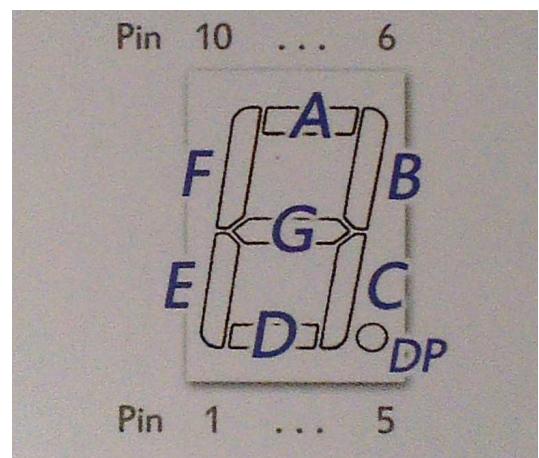

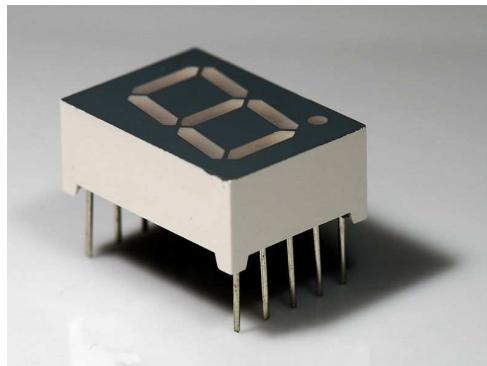

RPi.GPIO version 0.5.1a

```
GPIO.setup(17, GPIO.IN)

def my_callback():
    global time_stamp      # put in to debounce
    time_now = time.time()
    if (time_now - time_stamp) >= 0.05:
        print "Button Pressed"
    time_stamp = time_now

GPIO.add_event_detect(17, GPIO.FALLING, callback=my
_callback)
```

Experiment 2: Display digit on 7-segment LED

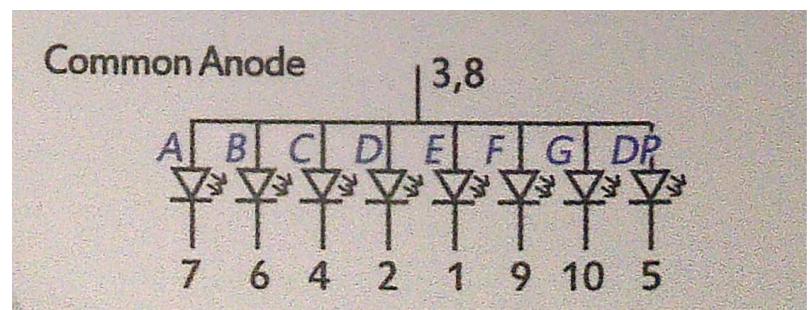

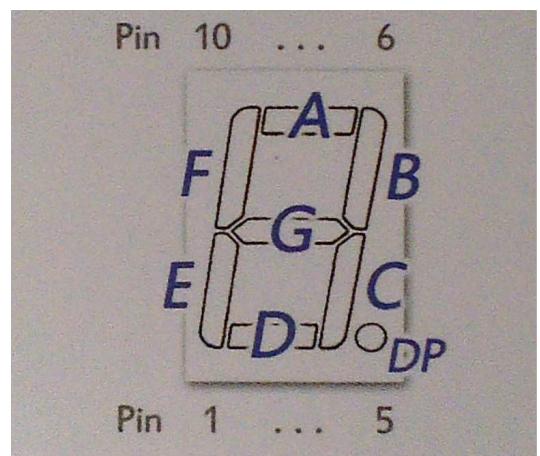

Experiment 2: Display digit on 7-segment LED

- Most direct way to control display:
 - Connect pin 3/8 of 7-seg-LED to Vcc
 - Connect the other 8 pins to 8 GPIO pins
 - Configure the 8 GPIO pins as output

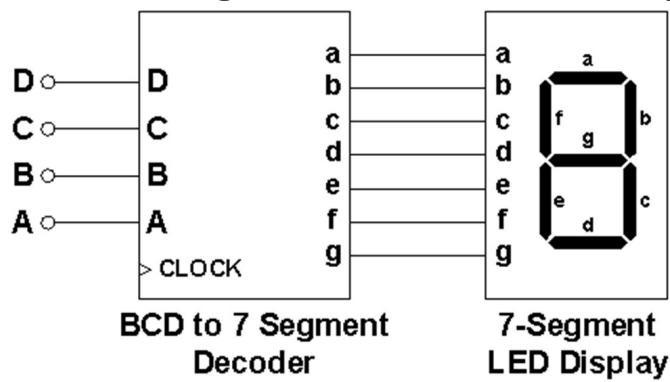

Experiment 2: Display digit on 7-segment LED

- For example: display “2”
 - Turn on segments A, B, D, E G.
and turn off segments C, F, DP
 - Set A,B,D,E,G to LOW
and set C, F, DP to HIGH
 - Set Pin 7, 6, 2, 1, 10 LOW

Set pin 4, 9, 5 HIGH

- The most direct way uses 8 GPIO pins.
- If we only display 0-9 digits, this is inefficient.
 - Use BCD to 7-segment decoder to display digit

- How to display multiple digits?

Using I2C: Control 4 digit 7-segment display

- How to do multiple 7-segment display?
 - Multiplexing
- The driver chip behind it will do this for us
- We can control it through I2C

Configure I2C

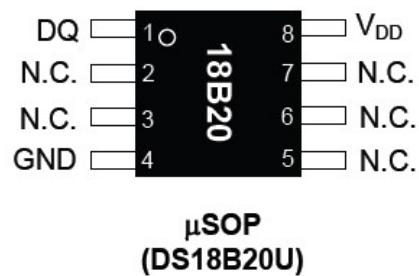

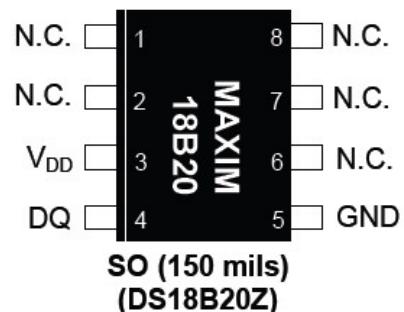

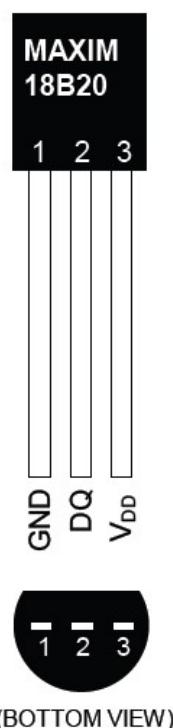

- Add modules
 - Add two modules to the end of file /etc/modules :
i2c-bcm2708
i2c-dev
- Install I2C tools utility
 - sudo apt-get install python-smbus
 - sudo apt-get install i2c-tools
 - If we have file: /etc/modprobe.d/raspi-blacklist.conf, comment the following two lines:
blacklist spi-bcm2708
blacklist i2c-bcm2708
- To see all the connected devices:
 - sudo i2cdetect -y 1

Control 4-digit 7-Segment Display

- Connect the 4 digit 7-segment display:
 - Four pins
 - Vcc, GND, SDA (Serial Data Line), SCL (Serial Clock)
- Use Adafruit's library to control the display:
<http://learn.adafruit.com/matrix-7-segment-led-backpack-with-the-raspberry-pi/using-the-adafruit-library>
- All the low level I/O: Adafruit_LEDBackpack.py
- 7-Segment Library: Adafruit_7Segment.py
 - **writeDigit(charNumber, value, dot=False)**
 - **setColon(state)**

Experiment 3: Temperature Sensor

- Maxim: DS18B20+
- Operating temperature: -55 °C to +125 °C
- Accuracy: 0.5 °C (-10 °C to +80 °C)
- Datasheet:
<http://datasheets.maximintegrated.com/en/ds/DS18B20.pdf>
- Request free sample at:
<http://www.maximintegrated.com/>

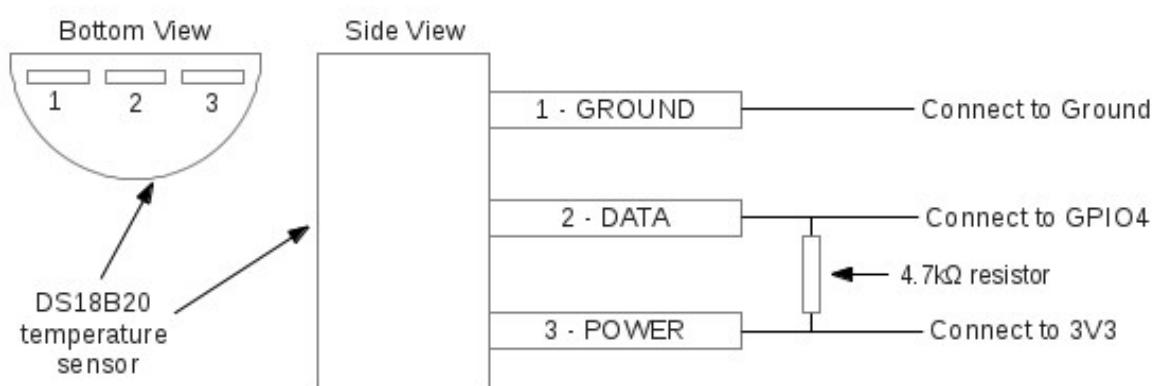

TO-92
(DS18B20)

DS18B20+ Features

- Unique 1-Wire® Interface Requires Only One Port Pin for Communication
- Each Device has a Unique 64-Bit Serial Code Stored on an On-Board ROM
- Requires No External Components
- Thermometer Resolution is User Selectable from 9 to 12 Bits
- Convert temperature to 12-Bit Digital Word in 750ms (max)

DS18B20+ connection diagram

This is a BOTTOM view. Identify GND and POWER correctly before you connect.

!!! Wrong connection of GND and POWER will burn the chip instantly.

How to read data from DS18B20+?

- Look at DS18B20+. Follow the 1-wire protocol.
 - **1-Wire** is a device communications bus system designed by Dallas Semiconductor Corp. that provides low-speed data, signaling, and power over a single signal.
 - Multiple 1-wire sensors can share the same pin
 - See <http://en.wikipedia.org/wiki/1-Wire> for details
 - <http://datasheets.maximintegrated.com/en/ds/DS18B20.pdf>

Read temperature

- We do not need to implement the 1-wire protocol ourselves.
- We can read temperature from a file
 - sudo modprobe w1-gpio
 - sudo modprobe w1-therm
 - cd /sys/bus/w1/devices
 - ls
 - cd 28-xxxx (may need change to match serial no.)
 - cat w1_slave

Read temperature

- In Python, we can read the temperature by parsing that file:

```
import os
import glob
import time
os.system('modprobe w1-gpio')
os.system('modprobe w1-therm')
base_dir = '/sys/bus/w1/devices/'
device_folder = glob.glob(base_dir + '28*')[0]
device_file = device_folder + '/w1_slave'
```

Python Socket Programming

- Two types of sockets:
 - Stream & datagram
 - `streamSock = socket.socket(socket.AF_INET, socket.SOCK_STREAM)`
 - `dgramSock = socket.socket(socket.AF_INET, socket.SOCK_DGRAM)`

Sample Code: Stream Client

```
import socket

clientSocket = socket.socket(socket.AF_INET,
socket.SOCK_STREAM)
clientSocket.connect(('192.168.2.10',23000))
clientSocket.send("Hello World\n")

# data receive from server and print
print clientSocket.recv(100)

clientSocket.close()
```

Sample Code: Stream Server

```
import socket

serverSocket = socket.socket(socket.AF_INET,
socket.SOCK_STREAM)
serverSocket.bind(('',23000))
serverSocket.listen( 5 )

while 1:
    # wait for client's connection
    clientSocket, (remoteHost, remotePort) =
serverSocket.accept()
    # receive data from client
    s = clientSocket.recv(100)
    # send data back to server
    clientSocket.send(s)
    clientSocket.close()
```

Experiment: LED controlled by remote sensor

- 1st Raspberry Pi board houses temperature sensor
- 2nd Raspberry Pi board houses an LED.
- The sensor reports the temperature to the 2nd Raspberry Pi board. LED will be turned on when the temperature is higher than a threshold.

IP Camera Setup

- Turn a USB-based camera to an IP camera
- Install “motion” package
 - sudo apt-get install motion
- Start “motion” service
 - sudo services motion start
- Configure “motion” in /etc/motion/motion.conf
 - Daemon = OFF to ON
 - webcam_localhost = ON to OFF
 - webcam_port = desired port number or 8088
 - control_port = desired port number or 8089

IP Camera Setup

- Let the motion service start automatically:

`sudo vi /etc/default/motion:`

“start_motion_daemon=no” to “yes”

- `sudo service motion restart`
- View video from webcam
 - <http://192.168.0.85:8088>
- Remotely control the web cam settings:
 - <http://192.168.0.85:8089>
